Tuberculosis in California (2005 to 2022)

Tuberculosis (TB) is a contagious bacterial infection primarily affecting the lungs, but it can also spread to other parts of the body.

Overview of Tuberculosis

- **Cause:** TB is caused by the bacterium *Mycobacterium tuberculosis*. It spreads through the air when an infected person coughs, sneezes, or talks, releasing tiny droplets containing the bacteria.
- **Types:** There are two main forms of TB:
 - **Latent TB:** The bacteria remain inactive in the body without causing symptoms. Individuals with latent TB are not contagious but can develop active TB later if their immune system weakens.
 - **Active TB:** This occurs when the bacteria multiply and cause symptoms. Active TB can be contagious and requires treatment.

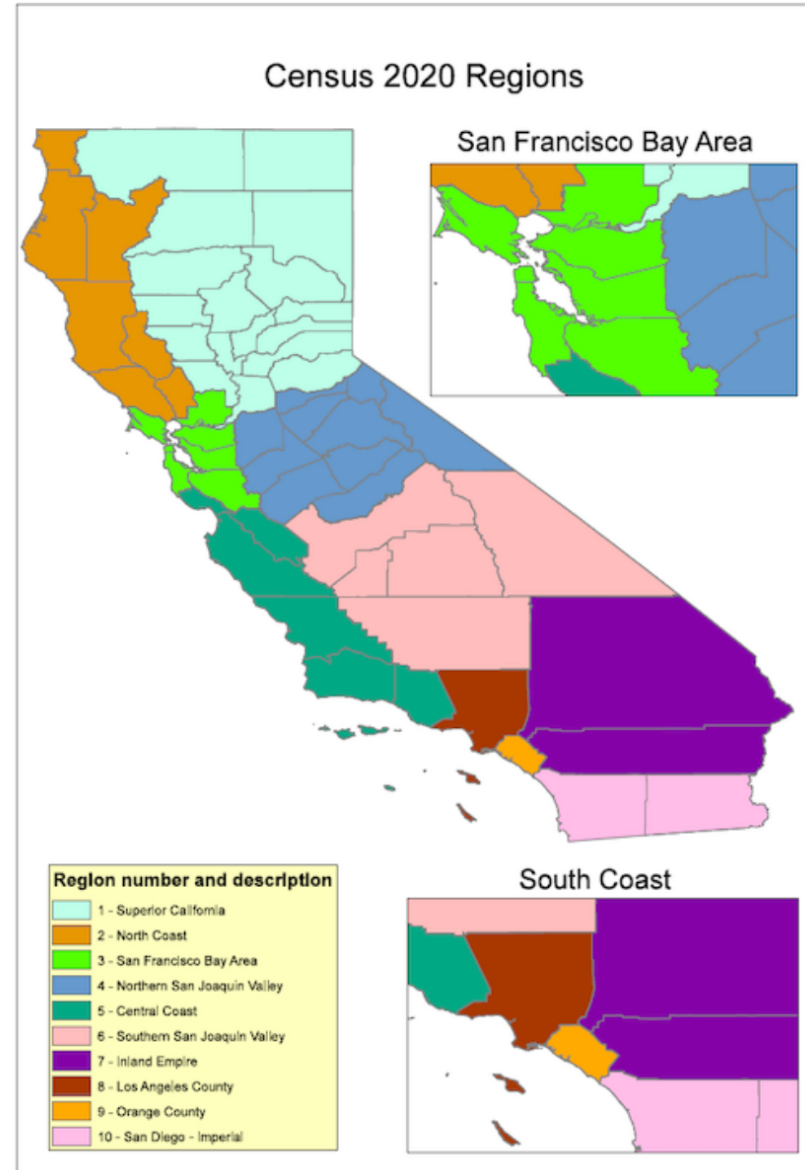

Symptoms

Symptoms of active TB can vary depending on the affected area but commonly include:

- Persistent cough (sometimes with blood or mucus)
- Chest pain
- Fatigue
- Fever and chills
- Night sweats
- Weight loss and loss of appetite.

Transmission

TB is primarily spread in crowded or poorly ventilated environments. People with weakened immune systems, such as those with HIV/AIDS, are at a higher risk of contracting TB.
